Revision History

Version	Date	Description of changes
1	2015-01-31	Initial version.
1.1	2015-05-14	Updated calculation of CVs. Switched density rasters to logarithmic breaks. No changes to the model.
1.2	2015-09-26	Updated the documentation. No changes to the model.

Total		895	8332	4

Table 2: Survey effort and sightings used in this model. Effort is tallied as the cumulative length of on-effort transects and hours the survey team was on effort. Sightings are the number of on-effort encounters of the modeled species for which a perpendicular sighting distance (PSD) was available. Off effort sightings and those without PSDs were omitted from the analysis.

Season	Months	Length (1000 km)	Hours	Sightings
All_Year	All	897	8332	4

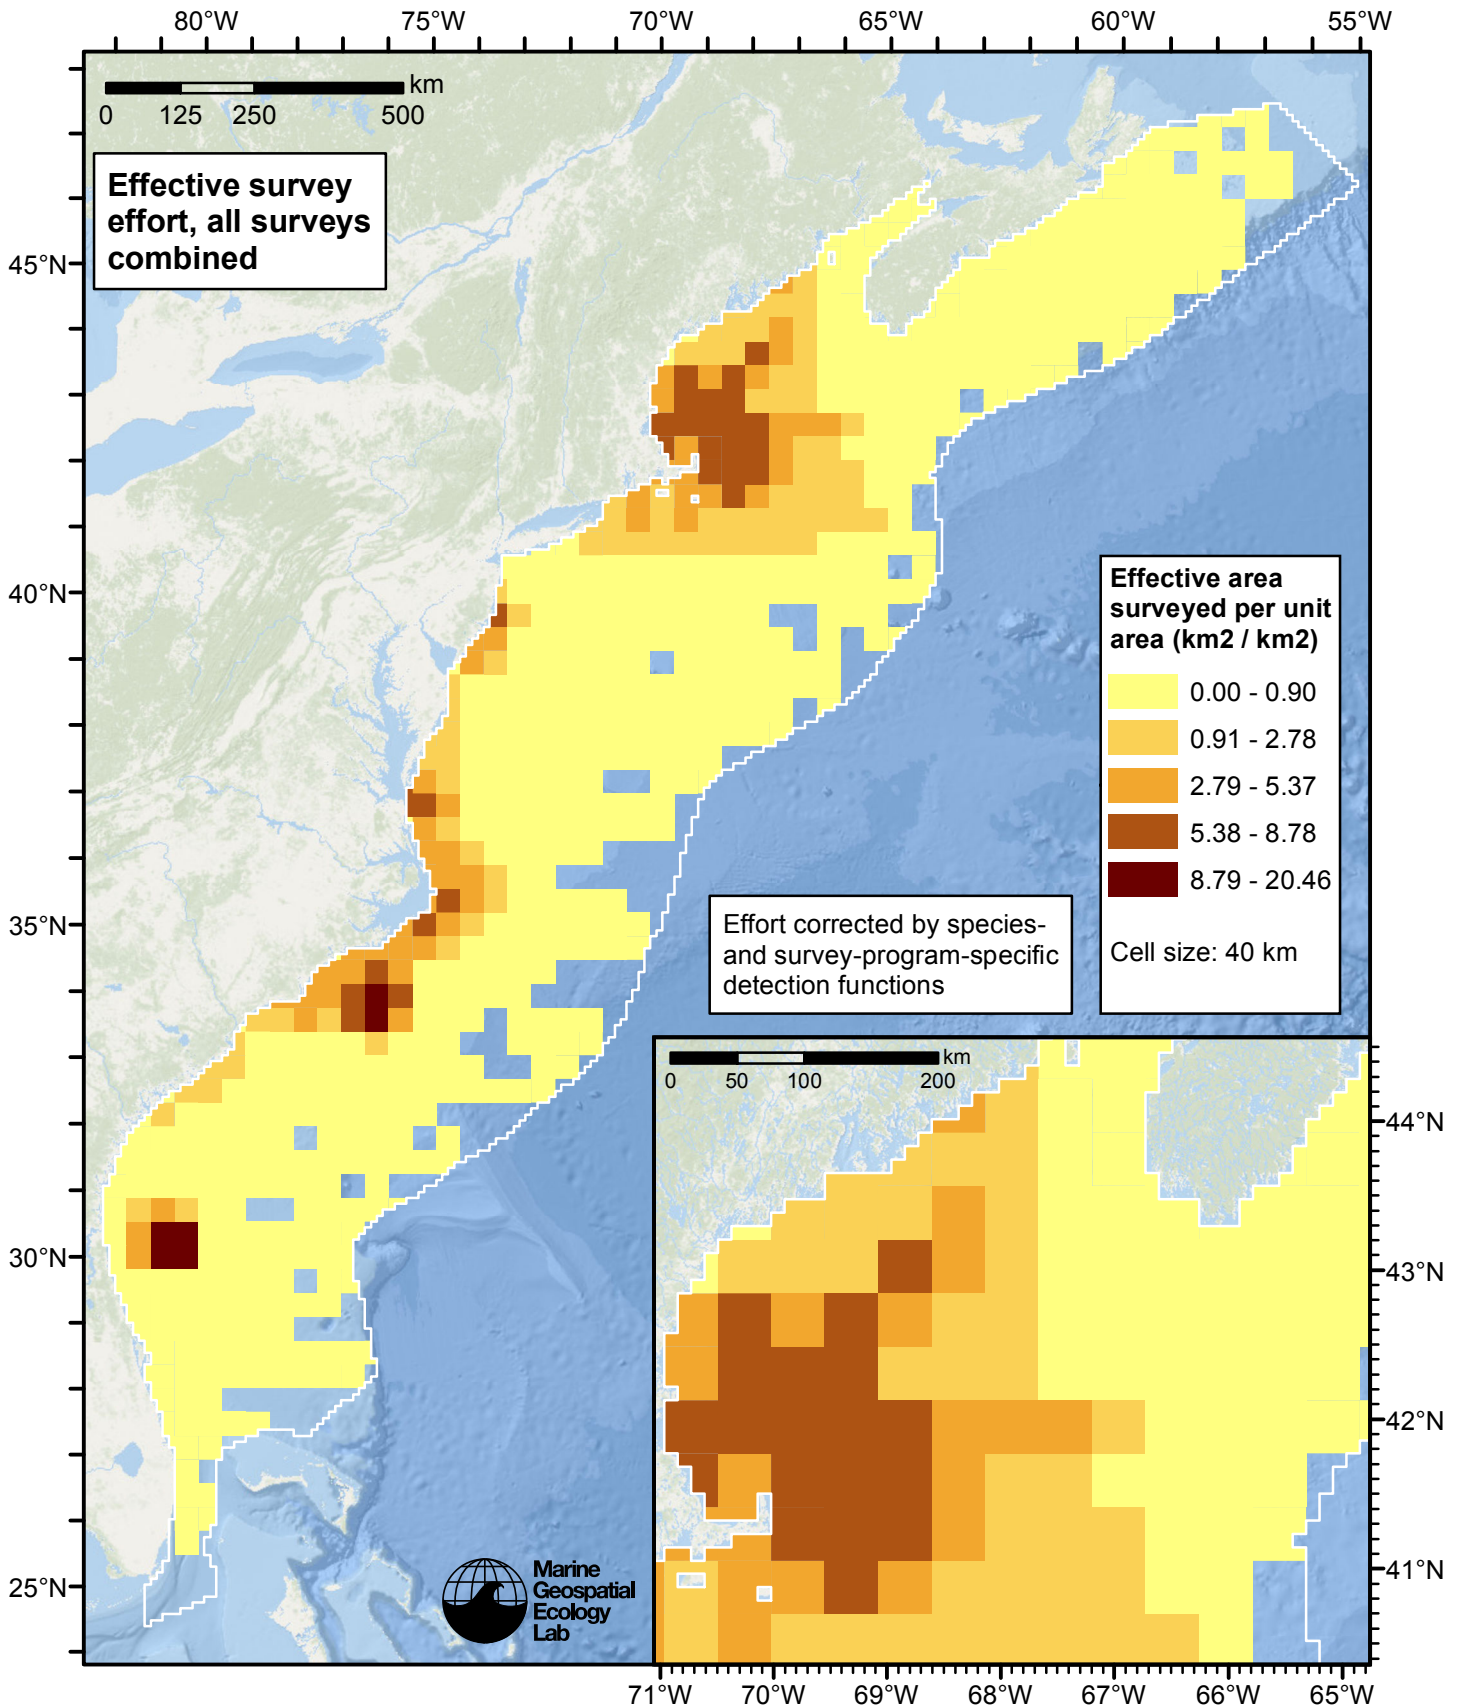

Figure 6: Effective survey effort per unit area, for all surveys combined. Here, effort is corrected by the species- and survey-program-specific detection functions used in fitting the density models.

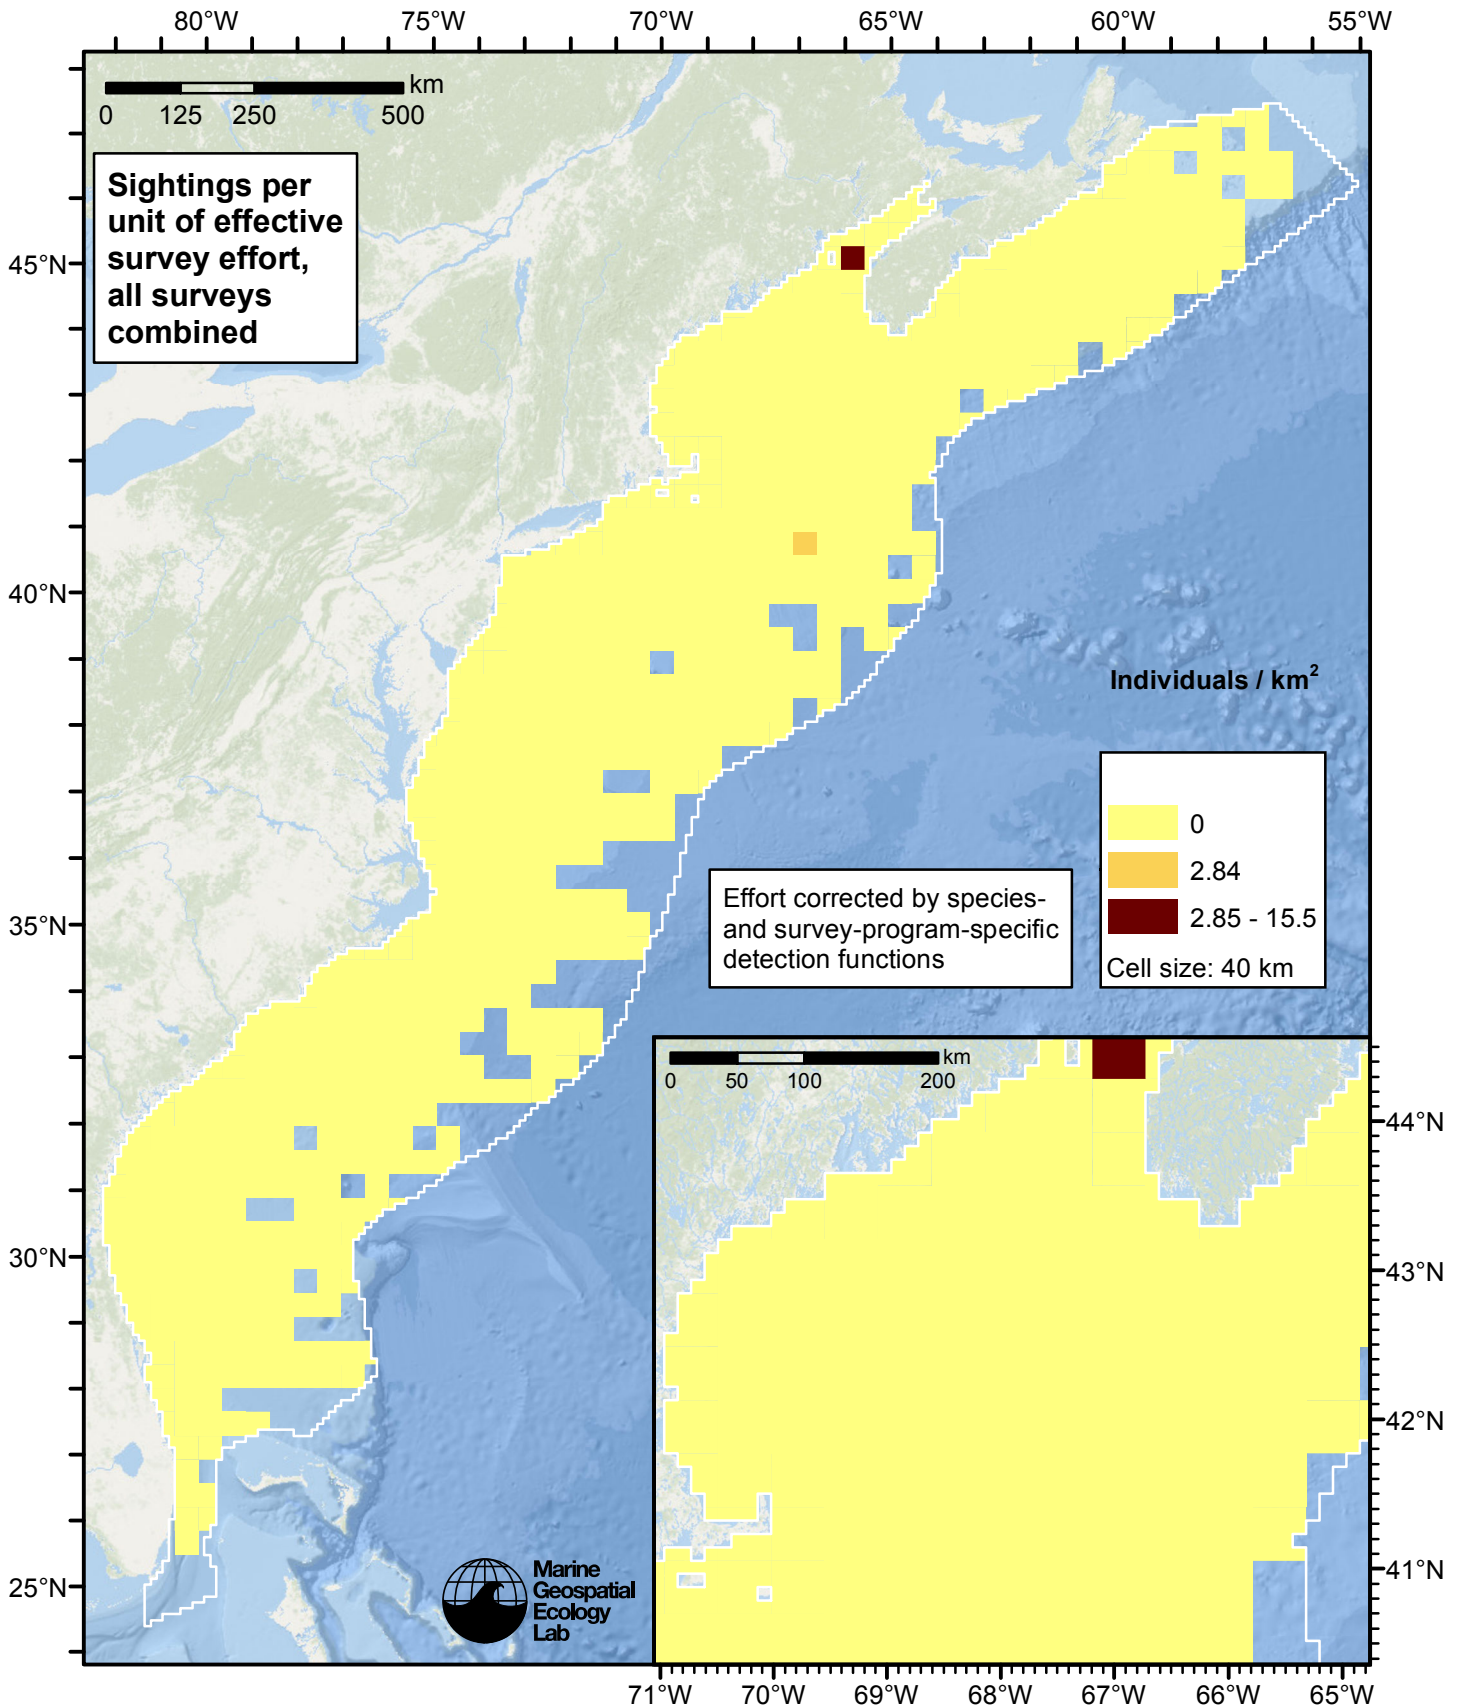

Figure 7: Killer whale sightings per unit of effective survey effort, for all surveys combined. Here, effort is corrected by the species- and survey-program-specific detection functions used in fitting the density models.

Detection Functions

The detection hierarchy figures below show how sightings from multiple surveys were pooled to try to achieve Buckland et. al's (2001) recommendation that at least 60-80 sightings be used to fit a detection function. Leaf nodes, on the right, usually represent individual surveys, while the hierarchy to the left shows how they have been grouped according to how similar we believed the surveys were to each other in their detection performance.

At each node, the red or green number indicates the total number of sightings below that node in the hierarchy, and is colored green if 70 or more sightings were available, and red otherwise. If a grouping node has zero sightings—i.e. all of the surveys within it had zero sightings—it may be collapsed and shown as a leaf to save space.

Each histogram in the figure indicates a node where a detection function was fitted. The actual detection functions do not appear in this figure; they are presented in subsequent sections. The histogram shows the frequency of sightings by perpendicular sighting distance for all surveys contained by that node. Each survey (leaf node) receives the detection function that is closest to it up the hierarchy. Thus, for common species, sufficient sightings may be available to fit detection functions deep in the hierarchy, with each function applying to only a few surveys, thereby allowing variability in detection performance between surveys to be addressed relatively finely. For rare species, so few sightings may be available that we have to pool many surveys together to try to meet Buckland's recommendation, and fit only a few coarse detection functions high in the hierarchy.

A blue Proxy Species tag indicates that so few sightings were available that, rather than ascend higher in the hierarchy to a point that we would pool grossly-incompatible surveys together, (e.g. shipboard surveys that used big-eye binoculars with those that used only naked eyes) we pooled sightings of similar species together instead. The list of species pooled is given in following sections.

Shipboard Surveys

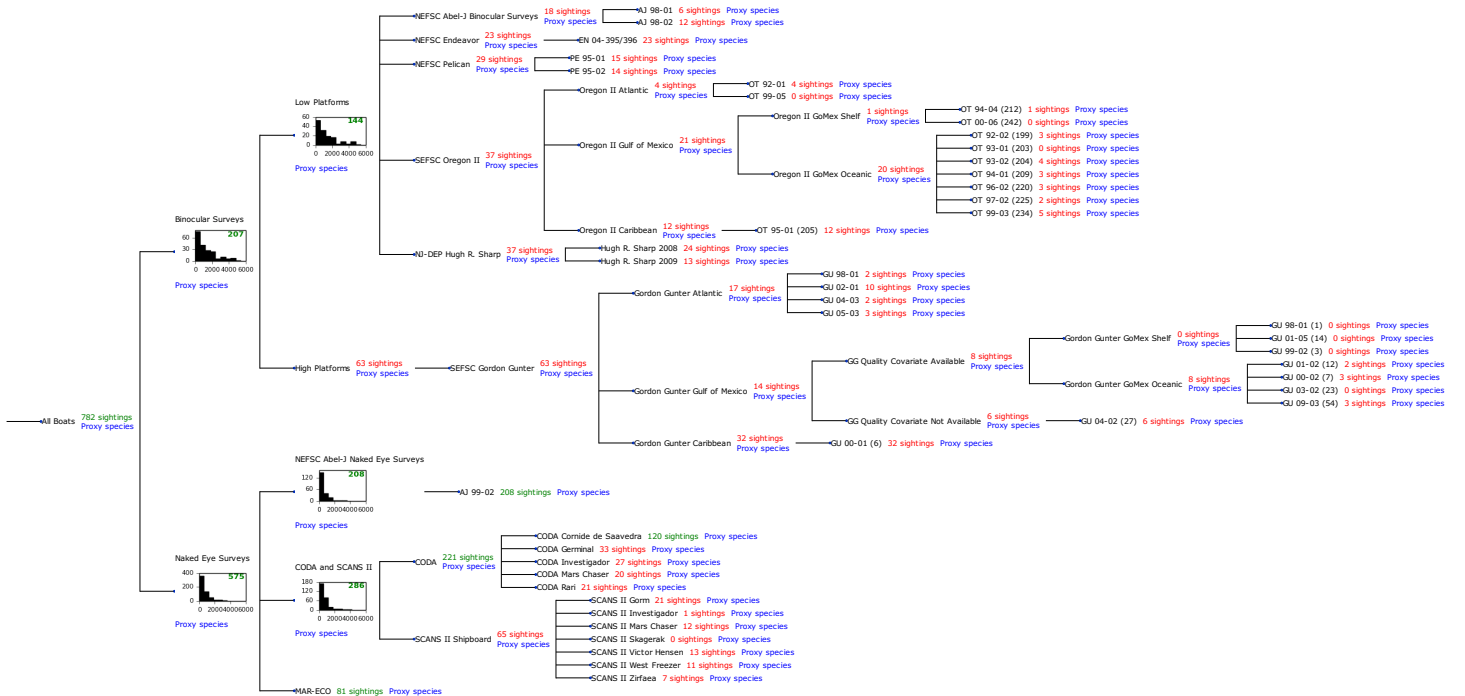

Figure 8: Detection hierarchy for shipboard surveys

Binocular Surveys

Because this taxon was sighted too infrequently to fit a detection function to its sightings alone, we fit a detection function to the pooled sightings of several other species that we believed would exhibit similar detectability. These “proxy species” are listed below.

Reported By Observer	Common Name	n
Balaenoptera	Balaenopterid sp.	8
Balaenoptera acutorostrata	Minke whale	4
Balaenoptera borealis	Sei whale	4
Balaenoptera borealis/edeni	Sei or Bryde’s whale	6
Balaenoptera borealis/physalus	Fin or Sei whale	0
Balaenoptera edeni	Bryde’s whale	21
Balaenoptera musculus	Blue whale	0
Balaenoptera physalus	Fin whale	98
Eubalaena glacialis	North Atlantic right whale	4
Eubalaena glacialis/Megaptera novaeangliae	Right or humpback whale	0
Megaptera novaeangliae	Humpback whale	46
Orcinus orca	Killer whale	16
Total		207

Table 4: Proxy species used to fit detection functions for Binocular Surveys. The number of sightings, n, is before truncation.

The sightings were right truncated at 5500m.

Covariate	Description
beaufort	Beaufort sea state.
size	Estimated size (number of individuals) of the sighted group.
vessel	Vessel from which the observation was made. This covariate allows the detection function to account for vessel-specific biases, such as the height of the survey platform.

Table 5: Covariates tested in candidate “multi-covariate distance sampling” (MCDS) detection functions.

Without Belly Observers - 600 ft

Because this taxon was sighted too infrequently to fit a detection function to its sightings alone, we fit a detection function to the pooled sightings of several other species that we believed would exhibit similar detectability. These “proxy species” are listed below.

Reported By Observer	Common Name	n
Balaenoptera	Balaenopterid sp.	2
Balaenoptera acutorostrata	Minke whale	8

Balaenoptera borealis	Sei whale	0
Balaenoptera borealis/edeni	Sei or Bryde’s whale	0
Balaenoptera borealis/physalus	Fin or Sei whale	0
Balaenoptera edeni	Bryde’s whale	0
Balaenoptera musculus	Blue whale	0
Balaenoptera physalus	Fin whale	15
Eubalaena glacialis	North Atlantic right whale	2
Eubalaena glacialis/Megaptera novaeangliae	Right or humpback whale	0
Megaptera novaeangliae	Humpback whale	16
Orcinus orca	Killer whale	2
Physeter macrocephalus	Sperm whale	10
Total		55

Table 22: Proxy species used to fit detection functions for Without Belly Observers - 600 ft. The number of sightings, n , is before truncation.

The sightings were right truncated at 600m. Due to a reduced frequency of sightings close to the trackline that plausibly resulted from the behavior of the observers and/or the configuration of the survey platform, the sightings were left truncated as well. Sightings closer than 32 m to the trackline were omitted from the analysis, and it was assumed that the area closer to the trackline than this was not surveyed. This distance was estimated by inspecting histograms of perpendicular sighting distances.

Covariate	Description
beaufort	Beaufort sea state.
size	Estimated size (number of individuals) of the sighted group.

Without Belly Observers - 750 ft

Because this taxon was sighted too infrequently to fit a detection function to its sightings alone, we fit a detection function to the pooled sightings of several other species that we believed would exhibit similar detectability. These “proxy species” are listed below.

Reported By Observer	Common Name	n
Balaenoptera	Balaenopterid sp.	1
Balaenoptera acutorostrata	Minke whale	0

Balaenoptera borealis	Sei whale	0
Balaenoptera borealis/edeni	Sei or Bryde's whale	2
Balaenoptera borealis/physalus	Fin or Sei whale	0
Balaenoptera edeni	Bryde's whale	3
Balaenoptera musculus	Blue whale	0
Balaenoptera physalus	Fin whale	2
Eubalaena glacialis	North Atlantic right whale	0
Eubalaena glacialis/Megaptera novaeangliae	Right or humpback whale	0
Megaptera novaeangliae	Humpback whale	6
Orcinus orca	Killer whale	0
Physeter macrocephalus	Sperm whale	37
Total		51

Table 25: Proxy species used to fit detection functions for Without Belly Observers - 750 ft. The number of sightings, n , is before truncation.

The sightings were right truncated at 600m. Due to a reduced frequency of sightings close to the trackline that plausibly resulted from the behavior of the observers and/or the configuration of the survey platform, the sightings were left truncated as well. Sightings closer than 40 m to the trackline were omitted from the analysis, and it was assumed that the area closer to the trackline than this was not surveyed. This distance was estimated by inspecting histograms of perpendicular sighting distances. The vertical sighting angles were heaped at 10 degree increments, so the candidate detection functions were fitted using linear bins scaled accordingly.

Group Size vs. Distance, right trunc. at 5000 m

Figure 53: Histograms showing group size frequency and scatterplots showing the relationship between group size and perpendicular sighting distance, for all sightings (top row) and only those not right truncated (bottom row). In the scatterplot, the line is a simple linear regression.

$g(0)$ Estimates

Platform	Surveys	Group Size	$g(0)$	Biases Addressed	Source
Shipboard	All	Any	0.921	Perception	Barlow and Forney (2007)
Aerial	All	Any	0.78	Availability	Hooker et al. (2012)

Table 39: Estimates of $g(0)$ used in this density model.

No species- or survey-specific estimates of $g(0)$ were available for killer whales for any surveys in our study. For shipboard surveys, we used Barlow and Forney’s (2007) estimate (0.921) for large whales (including killer whales) produced from several years of dual-team surveys in the Pacific ocean that used similar binoculars and protocols to the binocular surveys in our study. We also applied this estimate to the naked eye surveys in our study, as we found no estimate of $g(0)$ in the literature for killer whales observed by naked eye from shipboard surveys.

This estimate accounted for perception bias but not availability bias, but we do not believe availability to be a major factor affecting detectability of killer whales from shipboard surveys, as they are not a particularly long-diving species. For long diving cetaceans such as sperm whales, *Kogia* spp., and beaked whales, Barlow and Forney (2007) used Barlow’s (1999) model of $g(0)$ that incorporated dive behavior. Barlow parameterized that model such that the median duration of long dives ranged from 10.9-28.6 min, depending on the species, based on prior observational studies. By comparison, Baird et al. (2005) reported that mean dive durations for 41 fish-eating killer whales for dives ≥ 1 min in duration was 2.3-2.4 min. Miller et al. (2010) studied the diving behavior of 12 mammal-eating killer whales, which exhibited longer dives. The authors did not report dive duration statistics but noted that the whales spent 50% of their time 8 m or shallower and 90% of their time 40 m or shallower. Hooker et al. (2012) reported that unspecified killer whales spent 78% of their time between 0-10 m. Finally, Sivle et al. (2012) characterized killer whales as a “shallow-diving” odontocete; by contrast, they characterized pilot whales as “intermediate diving” and sperm whales as “deep diving” odontocetes.

We did not find a species-specific $g(0)$ estimate for killer whales observed by aircraft in the literature. Palka (2006) estimated of $g(0)$ for groups of 1-5 large whales from from two years of aerial surveys using the Hiby (1999) circle- back method. This estimate accounted for both availability and perception bias, but pooled sightings of several species together to provide a generic estimate for all large whales, due to sample-size limitations. Most of these species undertake longer dives than killer whales; we believe Palka’s $g(0)$ was dominated by availability bias of such species and thus underestimates killer whale detectability. Instead, we used Hooker et al.’s (2012) report that an unspecified number and type of killer whales spent 78% of time between 0-10 m and set $g(0)=0.78$.

We note that percent time spent at 0-10 m does not necessarily equate to “percent time detectable by aerial observation”. Hooker et al.’s data appear to be those reported by Kvadsheim et al. (2012). The four killer whales monitored in that study performed roughly 20x more dives to 1-30 m than to 30-200 m; the mean depth of the 1-30 m dives was only 2.6-3.6 m.

Density Model

Killer whales are widely distributed throughout the world’s oceans and are found in tropical, temperate, and high-latitude waters, in both pelagic and coastal habitats (Forney and Wade 2006). They are considered rare in the Gulf of Mexico, U.S. Atlantic waters, and the Bay of Fundy, uncommon but seasonally regular in Labrador and Newfoundland, and common in the Canadian Arctic (Forney and Wade 2006). A recent comprehensive analysis of available systematic and opportunistic sightings in the northwest Atlantic between 40-60 N, 40-75 W concurred with this view (Lawson and Stevens 2014). These authors reported that almost all of the sightings in this region occurred at depths less than 200m, but that this might reflect a bias in the distribution of observation effort, and that killer whales have been reported in mid-Atlantic waters at depths exceeding 3000m (Lawson and Stevens 2014). For the latitudes 25-45 N, the Ocean Biogeographic Information System Spatial Ecological Analysis of Megavertebate Populations (OBIS-SEAMAP) database reported sightings at depths ranging from less than 10m to more than 5000m; sightings were concentrated in the northern half of the region but were not absent from the southern half (<http://seamap.env.duke.edu/species/180469>, accessed January 30, 2015). Lawson and Stevens (2014) also reported that killer whales were sighted in their study area during all months of the year.

The surveys in our database reported only four killer whale sightings within our east coast study area. With so few sightings, we could not attempt to model abundance from environmental predictors. The wide distribution of sightings of killer whales, both globally and within our study area, suggested that our entire east coast study area is killer whale habitat, so we included the entire area in our stratified model.

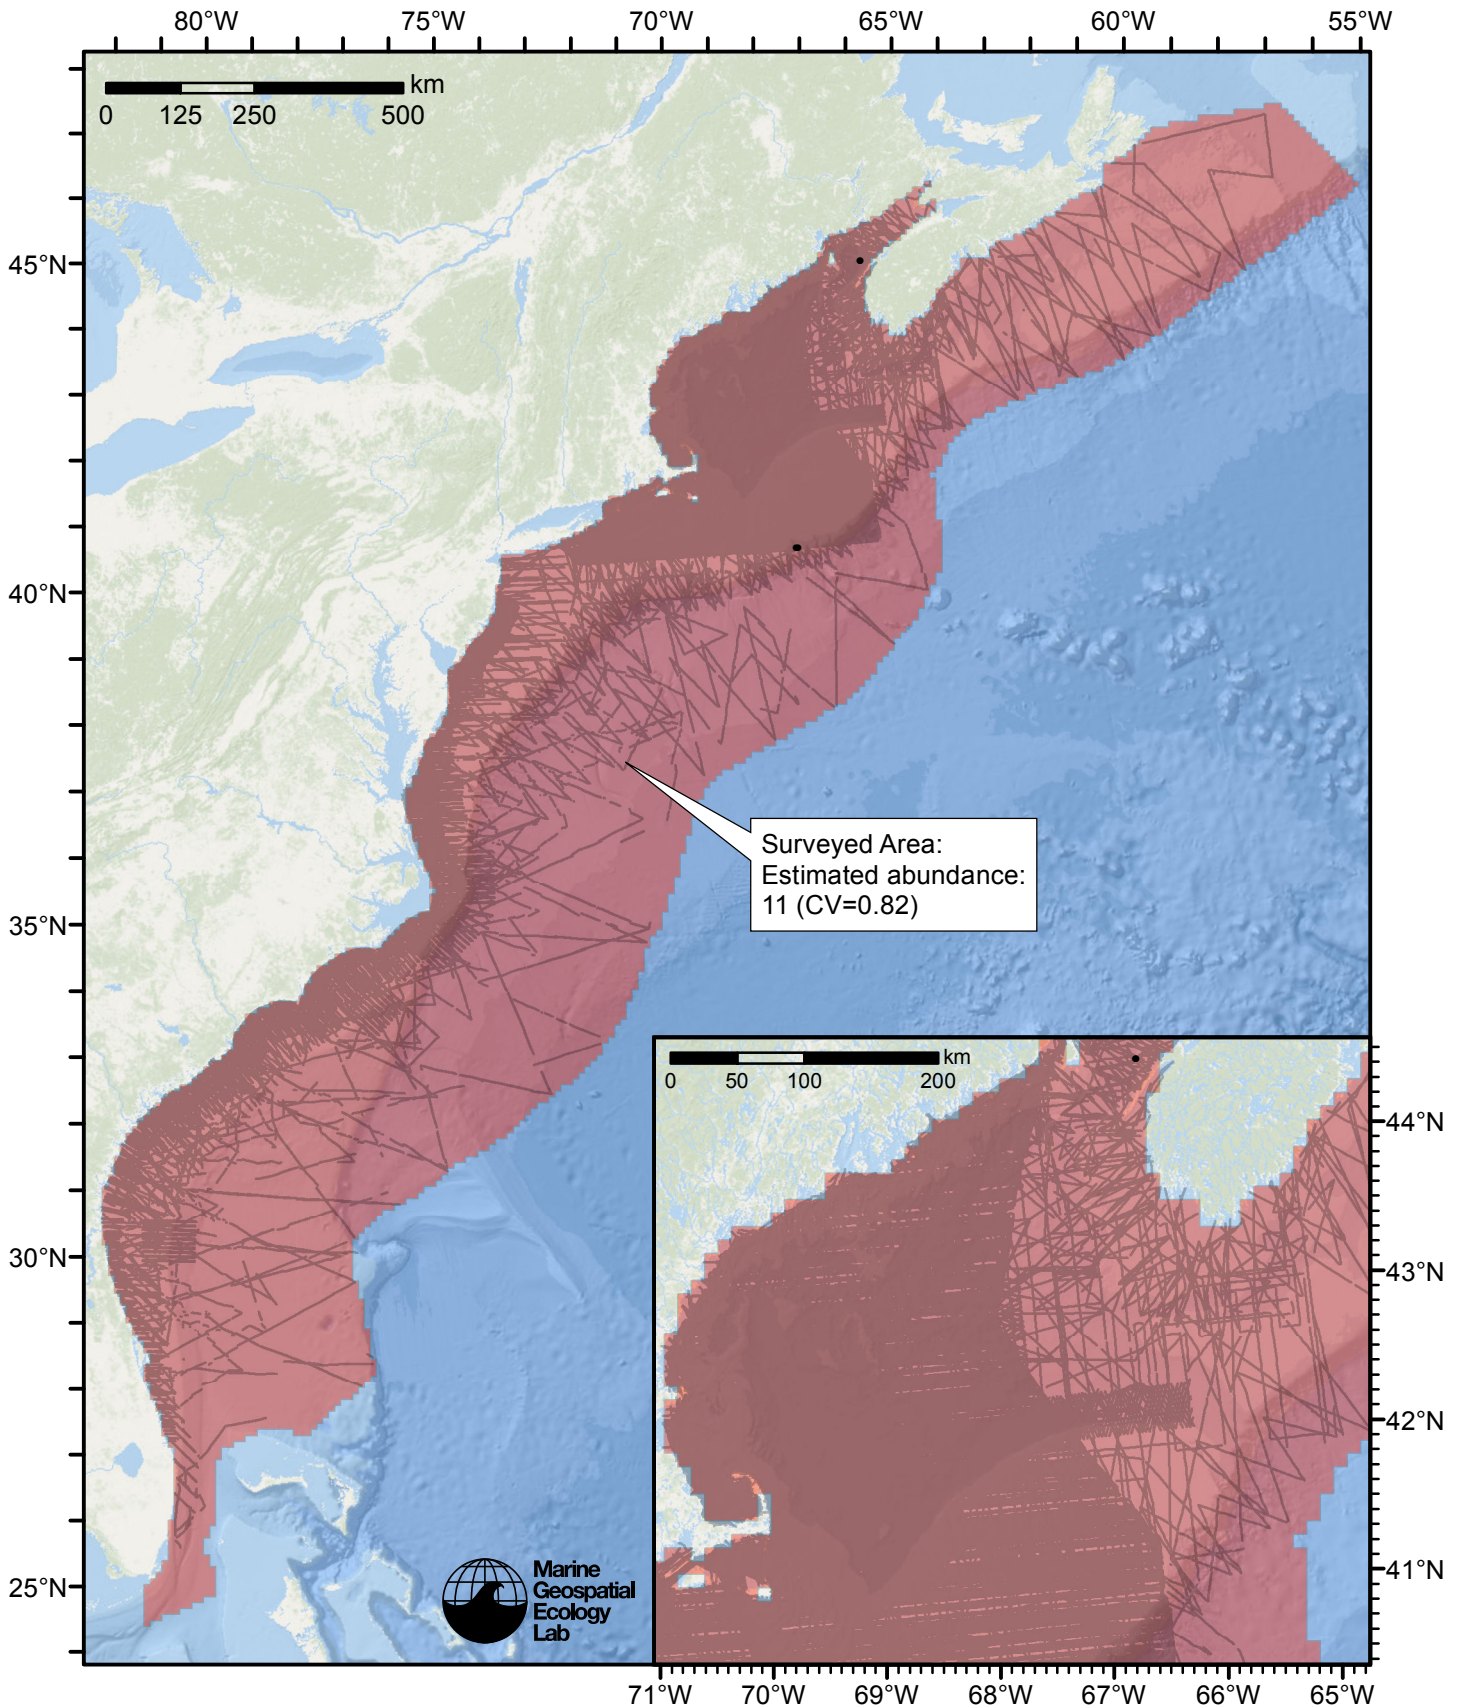

Figure 54: Killer whale density model schematic. All sightings are shown, including those that were truncated when detection functions were fitted. The coefficient of variation (CV) underestimates the true uncertainty of our estimate, as it only incorporated the uncertainty of the GAM stage of our model. Other sources of uncertainty include the detection functions and $g(0)$ estimates. It was not possible to incorporate these into our CV without undertaking a computationally-prohibitive bootstrap; we hope to attempt that in a future version of our model.

Abundance Estimates

Dates	Model or study	Estimated abundance	CV	Assumed $g(0)=1$	In our models
1992-2014	Our model	11	0.82	No	
1972-2012?	Minimum estimate for 40-60 N, 40-75 W from photo ID (Lawson and Stevens 2014)	67			

Table 40: Estimated mean abundance within the study area for our model and independent estimates from NOAA and/or the scientific literature. The Dates column gives the dates to which the estimates apply. For our model, these are the years for survey data were available. Our coefficient of variation (CV) estimates are probably too low, as they only incorporated the uncertainty of the GAM stage of our models. Other sources of uncertainty include the detection functions and $g(0)$ estimates. It was not possible to incorporate these into our CVs without undertaking a computationally-prohibitive bootstrap; we hope to attempt that in a future version of our models. The Assumed $g(0)=1$ column specifies whether the abundance estimate assumed that detection was certain along the survey trackline. Studies that assumed this did not correct for availability or perception bias, and therefore underestimated abundance. The In our models column specifies whether the survey data from the study was also used in our models. If not, the study provides a completely independent estimate of abundance. Note that our abundance estimates are averaged over the whole year, while the other estimates apply to specific months or seasons. Please see the Discussion section below for our evaluation of our models compared to the other estimates.

Discussion

At the time of this analysis, the most recent NOAA stock assessment report for the Western North Atlantic Stock of killer whales was from 2000 and it did not offer an abundance estimate. Lawson and Stevens (2014) reported a minimum number of 67 killer whales for the region 40-60 N, 40-75 W based on photographic identification of individuals, but that this is an underestimate of the true population. Of the 1700 photographs available, over 70% were not of sufficient quality to make an identification. They did not offer an estimate of the upper bound for the population but concluded that the northwestern Atlantic population is not as large as the northeastern Atlantic population, which may be close to 10,000 whales (Lawson and Stevens 2014).

In light of the uncertainty surrounding the population size but the general agreement that killer whales are rare within our study area, we believe our abundance estimate is not unreasonable.
