Revision History

Version	Date	Description of changes
1	2015-03-06	Initial version.
1.1	2015-05-14	Updated calculation of CVs. Switched density rasters to logarithmic breaks. No changes to the model.
1.2	2015-09-26	Updated the documentation. No changes to the model.

Table 2: Survey effort and sightings used in this model. Effort is tallied as the cumulative length of on-effort transects and hours the survey team was on effort. Sightings are the number of on-effort encounters of the modeled species for which a perpendicular sighting distance (PSD) was available. Off effort sightings and those without PSDs were omitted from the analysis.

Season	Months	Length (1000 km)	Hours	Sightings
All_Year	All	897	8332	4

Detection Functions

The detection hierarchy figures below show how sightings from multiple surveys were pooled to try to achieve Buckland et. al's (2001) recommendation that at least 60-80 sightings be used to fit a detection function. Leaf nodes, on the right, usually represent individual surveys, while the hierarchy to the left shows how they have been grouped according to how similar we believed the surveys were to each other in their detection performance.

At each node, the red or green number indicates the total number of sightings below that node in the hierarchy, and is colored green if 70 or more sightings were available, and red otherwise. If a grouping node has zero sightings—i.e. all of the surveys within it had zero sightings—it may be collapsed and shown as a leaf to save space.

Each histogram in the figure indicates a node where a detection function was fitted. The actual detection functions do not appear in this figure; they are presented in subsequent sections. The histogram shows the frequency of sightings by perpendicular sighting distance for all surveys contained by that node. Each survey (leaf node) receives the detection function that is closest to it up the hierarchy. Thus, for common species, sufficient sightings may be available to fit detection functions deep in the hierarchy, with each function applying to only a few surveys, thereby allowing variability in detection performance between surveys to be addressed relatively finely. For rare species, so few sightings may be available that we have to pool many surveys together to try to meet Buckland's recommendation, and fit only a few coarse detection functions high in the hierarchy.

A blue Proxy Species tag indicates that so few sightings were available that, rather than ascend higher in the hierarchy to a point that we would pool grossly-incompatible surveys together, (e.g. shipboard surveys that used big-eye binoculars with those that used only naked eyes) we pooled sightings of similar species together instead. The list of species pooled is given in following sections.

Shipboard Surveys

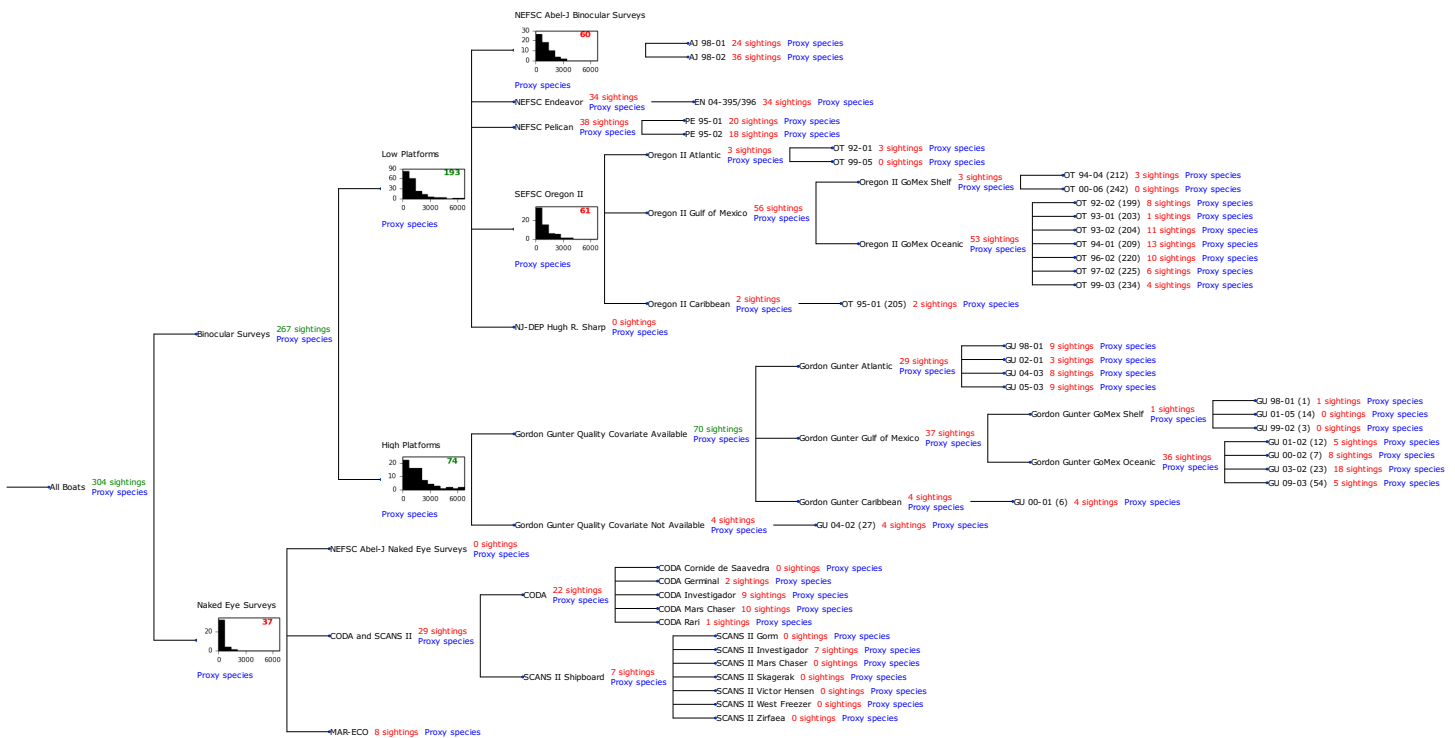

Figure 8: Detection hierarchy for shipboard surveys

Low Platforms

Because this taxon was sighted too infrequently to fit a detection function to its sightings alone, we fit a detection function to the pooled sightings of several other species that we believed would exhibit similar detectability. These “proxy species” are listed below.

Reported By Observer	Common Name	n
Hyperoodon ampullatus	Northern bottlenose whale	4
Mesoplodon	Beaked whale	110
Mesoplodon bidens	Sowerby’s beaked whale	14
Mesoplodon densirostris	Blainville’s beaked whale	5
Mesoplodon europaeus	Gervais’ beaked whale	0
Mesoplodon mirus	True’s beaked whale	2
Ziphiidae	Unidentified beaked whale	20
Ziphius cavirostris	Cuvier’s beaked whale	38
Total		193

Table 4: Proxy species used to fit detection functions for Low Platforms. The number of sightings, n, is before truncation.

The sightings were right truncated at 4000m.

Covariate	Description
beaufort	Beaufort sea state.
size	Estimated size (number of individuals) of the sighted group.

Table 5: Covariates tested in candidate “multi-covariate distance sampling” (MCDS) detection functions.

NARWSS Grumman's

Because this taxon was sighted too infrequently to fit a detection function to its sightings alone, we fit a detection function to the pooled sightings of several other species that we believed would exhibit similar detectability. These “proxy species” are listed below.

Reported By Observer	Common Name	n
Balaenoptera acutorostrata	Minke whale	88
Hyperoodon ampullatus	Northern bottlenose whale	0

Kogia	Pygmy or dwarf sperm whale	0
Kogia breviceps	Pygmy sperm whale	0
Kogia sima	Dwarf sperm whale	0
Mesoplodon	Beaked whale	0
Mesoplodon bidens	Sowerby’s beaked whale	0
Mesoplodon densirostris	Blainville’s beaked whale	0
Mesoplodon europaeus	Gervais’ beaked whale	0
Mesoplodon mirus	True’s beaked whale	0
Ziphiidae	Unidentified beaked whale	0
Ziphius cavirostris	Cuvier’s beaked whale	0
Total		88

Ziphius cavirostris	Cuvier’s beaked whale	0
Total		738

Table 24: Proxy species used to fit detection functions for NARWSS Twin Otters. The number of sightings, n , is before truncation.

The sightings were right truncated at 2000m. Due to a reduced frequency of sightings close to the trackline that plausibly resulted from the behavior of the observers and/or the configuration of the survey platform, the sightings were left truncated as well. Sightings closer than 107 m to the trackline were omitted from the analysis, and it was assumed that the area closer to the trackline than this was not surveyed. This distance was estimated by inspecting histograms of perpendicular sighting distances. The vertical sighting angles were heaped at 10 degree increments up to 80 degrees and 1 degree increments thereafter, so the candidate detection functions were fitted using linear bins scaled accordingly.

Covariate	Description
beaufort	Beaufort sea state.
quality	Survey-specific index of the quality of observation conditions, utilizing relevant factors other than Beaufort sea state (see methods).
size	Estimated size (number of individuals) of the sighted group.

$g(0)$ Estimates

Platform	Surveys	Group Size	$g(0)$	Biases Addressed	Source
Shipboard	All	Any	0.49	Perception	Palka (2006)
Shipboard	NEFSC Endeavor	Any	0.49	Perception	Palka (2006)
Aerial	All	Any	0.187	Availability	Hooker et al. (2009)

Table 27: Estimates of $g(0)$ used in this density model.

Palka (2006) provided a survey-specific, species-specific $g(0)$ estimate (0.49) for northern bottlenose whales sighted on NOAA NEFSC’s 2004 Endeavor shipboard survey. This survey used a dual-team methodology to account for perception bias. It did not account for availability bias (Palka 2005b). We used Palka’s $g(0)$ estimate for the lower team, which was the primary team and the one for which we had sightings.

Similar to other beaked whales, northern bottlenose whales are a long-diving species for which availability bias could be significant, as animals might be submerged for a substantial proportion of the time that their surface position would be visible to transiting shipboard observers. Barlow (1999) built a simulation model for $g(0)$ that accounted for both availability and perception bias for long-diving animals observed on shipboard surveys that utilized 25x binoculars. He reported $g(0)$ estimates of 0.23 and 0.45 for *Ziphius cavirostris* (Cuvier’s beaked whale) and a group of several species of the *Mesoplodon* genus, respectively. While he did not report an estimate for bottlenose whales, we considered the possibility of using his *Z. cavirostris* or *Mesoplodon* spp. estimate as a substitute, as follows.

First, using the median durations of long dives and surfacing series reported by Barlow (his Table 3), we estimated that his *Z. cavirostris* and *Mesoplodon* spp. spent 6.8% and 10.7% of their time at the surface. His data were based on dive behavior observed visually during NOAA research cruises. Next, we computed time-at-surface percentages for two *Z. cavirostris* and two *Mesoplodon densirostris* monitored with time depth recorders (Baird et al. 2006, Baird et al. 2008), as reported by Hooker et al. (2009). Using the mean dive and surface interval durations for all dives listed in Table 2 of Hooker et al. ($n=125$ for *Z. cavirostris*, $n=431$ for *M. densirostris*), we obtained a time-at-surface of 4.9% and 10.2%, respectively, for the two species. Finding these percentages roughly comparable to those we obtained from Barlow’s data, we then computed the time-at-surface percentage for all dives reported by Hooker et al. for two northern bottlenose whales ($n=179$), obtaining 16.9%.

Although the data are very sparse, Hooker et al.’s northern bottlenose whales spent more time at the surface than either *Z. cavirostris* or *M. densirostris*. Despite performing the deepest dives of the three species, the northern bottlenose whales had the shortest mean dive durations for all three dives classes analyzed by Hooker et al. (see their Table 2). Together, these results suggest that northern bottlenose whales may be available at the surface more than *Z. cavirostris* or *Mesoplodon* spp. Barlow estimated $g(0)=0.45$ for *Mesoplodon* spp., this might be a reasonable lower bound for $g(0)$ for northern bottlenose whale. Given that, we opted to apply Palka’s estimate of 0.49 to all shipboard surveys in our study. While this decision is based on sparse data, its effect on our model is limited: only one northern bottlenose whale was sighted on any other shipboard survey in our study (on the Abel-J in 1998).

We found no estimate of $g(0)$ in the literature for northern bottlenose whales sighted on aerial surveys. Utilizing equation (3) of Carretta et al. (2000) (which follows Barlow et al. 1988), we computed the availability bias component of $g(0)$ (0.187) from the mean surface and dive intervals (90.1 s and 7.40 min) for all dives recorded for two northern bottlenose whales ($n=179$), as reported by Hooker et al. (2009). We did not incorporate an estimate of perception bias so our $g(0)$ estimate is likely to be biased high. In any case, the value of $g(0)$ for aerial surveys has no effect on our model, as no northern bottlenose whales were sighted on any of our aerial surveys.

Density Model

A recent review of northern bottlenose whale population structure in the North Atlantic reported that they are found north of approximately 37.5 N and deeper than 500m, but seem to prefer depths between 800-1800m along the continental slope (Whitehead and Hooker 2012). They are extremely uncommon or rare in waters of the U.S. Exclusive Economic Zone (Waring et al. 2009). Farther north, along the Scotian Shelf, they are more common, especially near submarine canyons known as

the Gully, Shortland Canyon, and Haldimand Canyon (Wimmer and Whitehead 2004). The mean size of the Scotian Shelf population was estimated by photo identification mark-recapture methodology to be 163, including adults and immature animals (Whitehead and Wimmer 2005, Whitehead and Hooker 2012). Individuals do move between the canyons but do not appear to seasonally migrate (Wimmer and Whitehead 2004). The Scotian Shelf population appears to be genetically distinct from the two other closest known populations, in northern Labrador and northern Iceland (Dalebout et al. 2006).

The surveys in our database reported only four sightings. All were deeper than 500m and were south and east of Georges Bank. The surveys reported no sightings on the Scotian Shelf or its continental slope.

With so few sightings, we could not attempt to model abundance from environmental predictors. To reflect the findings reported in the literature, we split the study area at the 500m depth contour and along the center of the Gulf Stream (identifying its mean position from a 22 year climatology computed from Aviso daily geostrophic currents). We used the Gulf Stream as the southernmost limit of the species range rather than the latitude 37.5 N reported by Whitehead and Hooker (2012) because the Gulf Stream is the dominant oceanographic feature that divides ecological regions in the area. In the northern, off-shelf area, where the four northern bottlenose whale sightings occurred, we estimated mean density. In the southern and on-shelf area, where no sightings occurred, we assumed the species was absent. This was consistent with a compilation of sightings reported by Wimmer and Whitehead (2004).

We split the study area again at the approximate boundary between the Gulf of Maine and the Scotian Shelf. Survey effort was relatively sparse on the Scotian Shelf and our surveys reported no sightings, even though the canyons along the continental slope here are known to support a population of northern bottlenose whales, and that Canada Department of Fisheries and Oceans and others have reported sightings on the shelf itself (Wimmer and Whitehead 2004). Given the possible habitat differences between the Scotian Shelf and the area southwest of it where our sightings occurred, we elected not to offer an abundance prediction for the Scotian Shelf as part of this project.

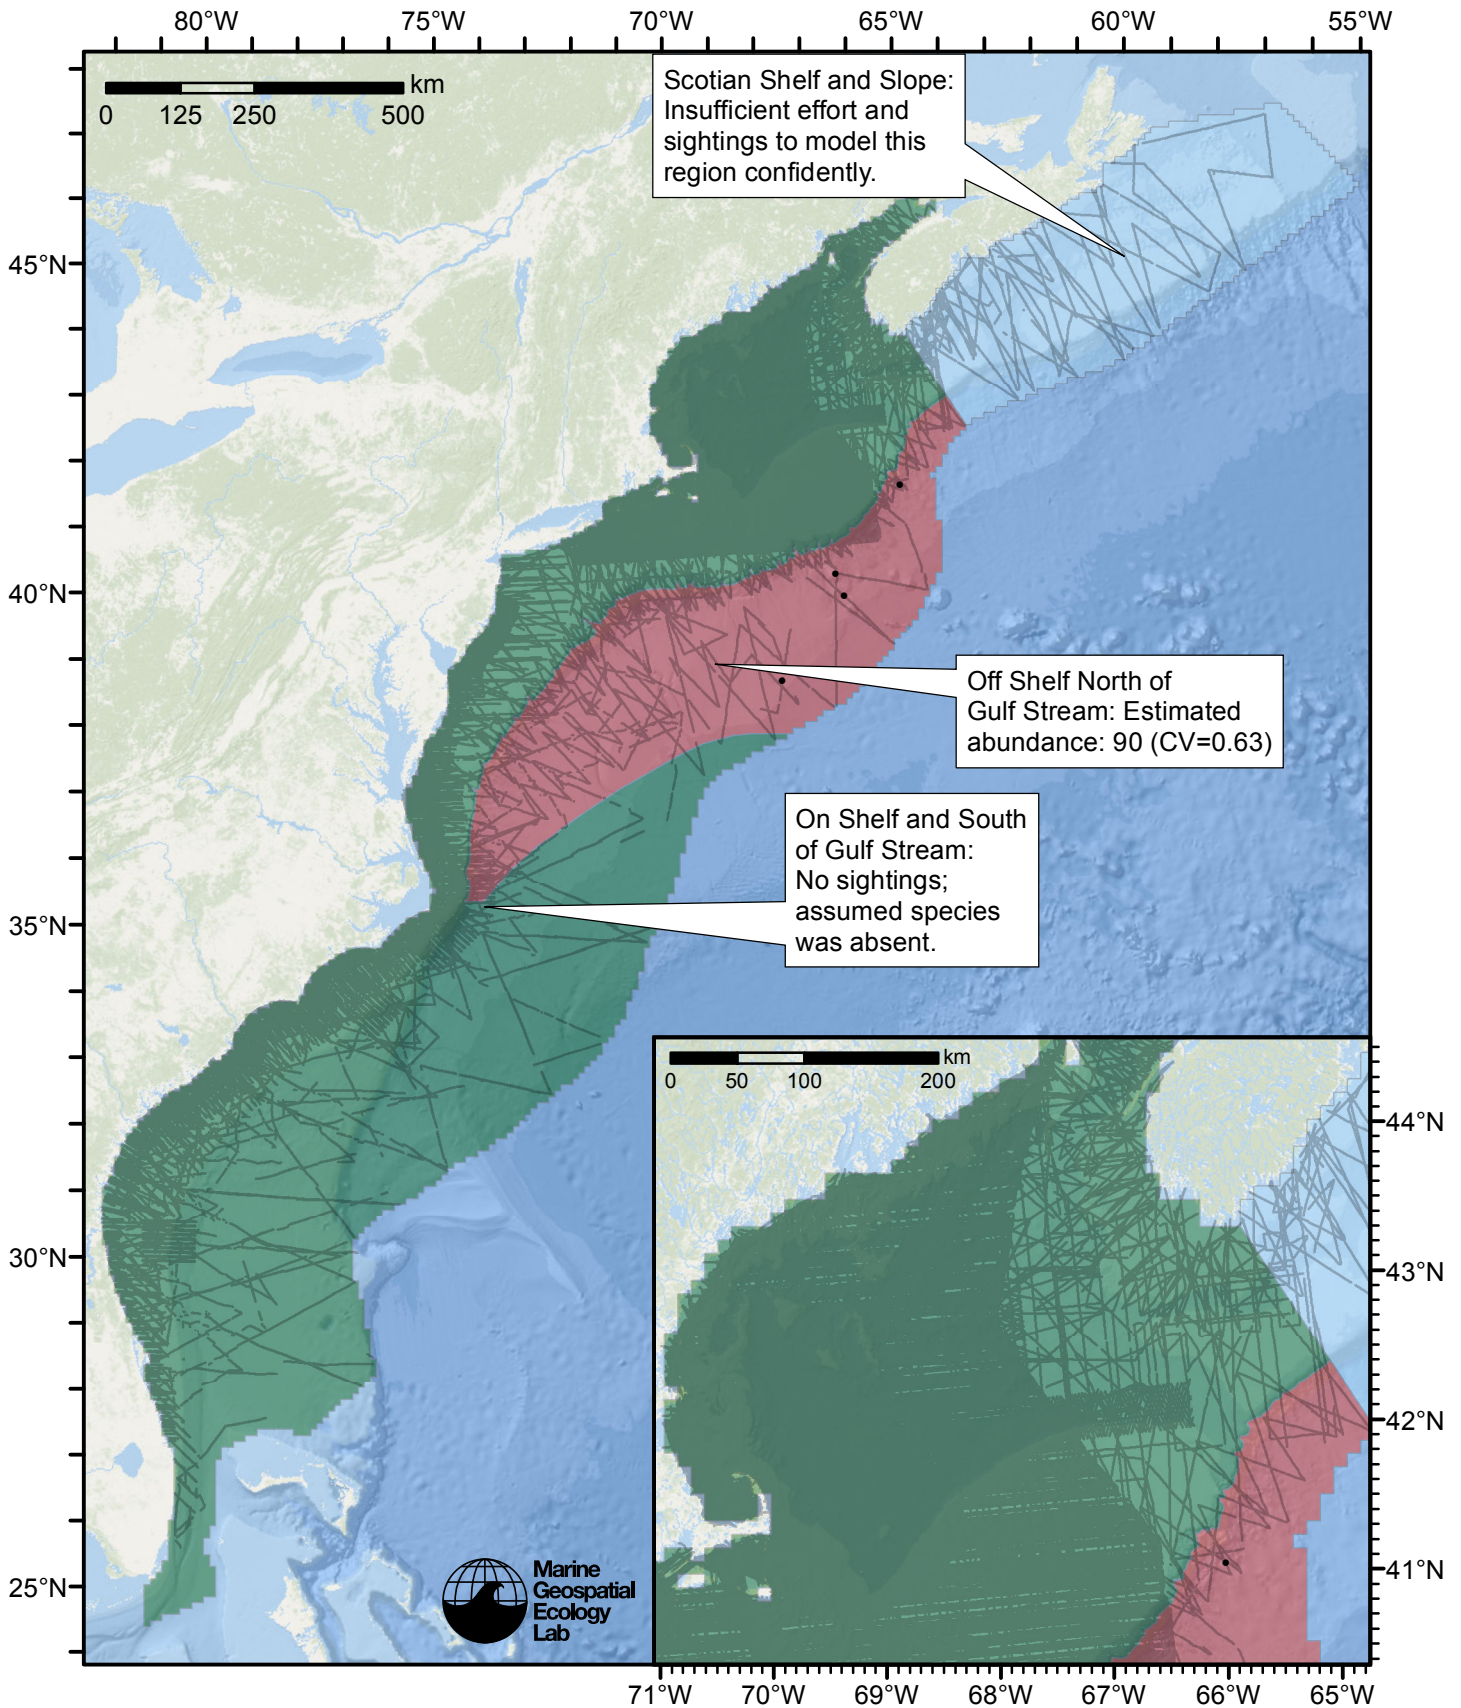

Figure 37: Northern bottlenose whale density model schematic. All sightings are shown, including those that were truncated when detection functions were fitted. The coefficient of variation (CV) underestimates the true uncertainty of our estimate, as it only incorporated the uncertainty of the GAM stage of our model. Other sources of uncertainty include the detection functions and $g(0)$ estimates. It was not possible to incorporate these into our CV without undertaking a computationally-prohibitive bootstrap; we hope to attempt that in a future version of our model.

Abundance Estimates

Dates	Model or study	Estimated abundance	CV	Assumed $g(0)=1$	In our models
1995-2013	Our model	90	0.63	No	
1998-2003	Scotian Shelf population, photo ID mark-recapture (Whitehead and Wimmer 2005)	163			

Table 28: Estimated mean abundance within the study area for our model and independent estimates from NOAA and/or the scientific literature. The Dates column gives the dates to which the estimates apply. For our model, these are the years for survey data were available. Our coefficient of variation (CV) estimates are probably too low, as they only incorporated the uncertainty of the GAM stage of our models. Other sources of uncertainty include the detection functions and $g(0)$ estimates. It was not possible to incorporate these into our CVs without undertaking a computationally-prohibitive bootstrap; we hope to attempt that in a future version of our models. The Assumed $g(0)=1$ column specifies whether the abundance estimate assumed that detection was certain along the survey trackline. Studies that assumed this did not correct for availability or perception bias, and therefore underestimated abundance. The In our models column specifies whether the survey data from the study was also used in our models. If not, the study provides a completely independent estimate of abundance. Note that our abundance estimates are averaged over the whole year, while the other estimates apply to specific months or seasons. Please see the Discussion section below for our evaluation of our models compared to the other estimates.

Discussion

At the time of this writing, NOAA had never produced an abundance estimate for northern bottlenose whales in the north Atlantic. The only other relevant estimate we identified in the literature was Whitehead and Wimmer's (2005) estimate of 163 animals for the Scotian Shelf population. The Scotian Shelf presumably represents better habitat than the area to which our estimate applies. We consider our estimate not implausible, as it is lower than Whitehead and Wimmer's estimate for the Scotian Shelf.

Lawson and Gosselin (2009) reported three sightings of northern bottlenose whales on the Scotian Shelf as part of the Canadian TNASS survey but did not estimate abundance. We made several attempts to contact J. Lawson but received no response. We remain hopeful that a collaboration can be established in the future, and that the Canadian TNASS data may be incorporated into a new version of our model. This may permit us to offer an abundance estimate for the Scotian Shelf.
