## Revision History

| Version | Date | Description of changes |
| :--- | :--- | :--- |
| 1 | $2014-10-19$ | Initial version. |
| 2 | $2014-11-21$ | Reconfigured detection hierarchy and adjusted NARWSS detection functions based on <br> additional information from Tim Cole. Removed CumVGPM180 predictor. Updated <br> documentation. |
| 3 | $2014-12-05$ | Fixed bug that applied the wrong detection function to segments <br> NE_narwss_1999_widgeon_hapo dataset. Refitted model. Updated documentation. |
| 3.1 | $2015-03-06$ | Updated the documentation. No changes to the model. |
| 3.2 | $2015-05-14$ | Updated calculation of CVs. Switched density rasters to logarithmic breaks. No changes <br> to the model. |
| 3.3 | $2016-04-21$ | Switched calculation of monthly $5 \%$ and 95\% confidence interval rasters to the method <br> used to produce the year-round rasters. (We intended this to happen in version 3.2 but I <br> did not implement it properly.) No changes to the other rasters or the model itself. |

| Virginia Aquarium Aerial Surveys | $2012-2014$ | 9 | 53 | 0 |
| Total |  | 895 | 8332 | 721 |

Table 2: Survey effort and sightings used in this model. Effort is tallied as the cumulative length of on-effort transects and hours the survey team was on effort. Sightings are the number of on-effort encounters of the modeled species for which a perpendicular sighting distance (PSD) was available. Off effort sightings and those without PSDs were omitted from the analysis.

| Season | Months | Length $(1000 \mathrm{~km})$ | Hours | Sightings |
| :--- | :--- | ---: | ---: | ---: |
| All_Year | All | 897 | 8332 | 721 |

Table 3: Survey effort and on-effort sightings having perpendicular sighting distances.

Figure 3: Risso's dolphin sightings per unit aerial linear survey effort.

Figure 4: Shipboard linear survey effort per unit area.

Figure 5: Risso's dolphin sightings per unit shipboard linear survey effort.

Figure 6: Effective survey effort per unit area, for all surveys combined. Here, effort is corrected by the species- and survey-program-specific detection functions used in fitting the density models.

Figure 7: Risso's dolphin sightings per unit of effective survey effort, for all surveys combined. Here, effort is corrected by the species- and survey-program-specific detection functions used in fitting the density models.

## Detection Functions

The detection hierarchy figures below show how sightings from multiple surveys were pooled to try to achieve Buckland et. al's (2001) recommendation that at least $60-80$ sightings be used to fit a detection function. Leaf nodes, on the right, usually represent individual surveys, while the hierarchy to the left shows how they have been grouped according to how similar we believed the surveys were to each other in their detection performance.

At each node, the red or green number indicates the total number of sightings below that node in the hierarchy, and is colored green if 70 or more sightings were available, and red otherwise. If a grouping node has zero sightings-i.e. all of the surveys within it had zero sightings-it may be collapsed and shown as a leaf to save space.

Each histogram in the figure indicates a node where a detection function was fitted. The actual detection functions do not appear in this figure; they are presented in subsequent sections. The histogram shows the frequency of sightings by perpendicular sighting distance for all surveys contained by that node. Each survey (leaf node) recieves the detection function that is closest to it up the hierarchy. Thus, for common species, sufficient sightings may be available to fit detection functions deep in the hierarchy, with each function applying to only a few surveys, thereby allowing variability in detection performance between surveys to be addressed relatively finely. For rare species, so few sightings may be available that we have to pool many surveys together to try to meet Buckland's recommendation, and fit only a few coarse detection functions high in the hierarchy.

A blue Proxy Species tag indicates that so few sightings were available that, rather than ascend higher in the hierarchy to a point that we would pool grossly-incompatible surveys together, (e.g. shipboard surveys that used big-eye binoculars with those that used only naked eyes) we pooled sightings of similar species together instead. The list of species pooled is given in following sections.

## Shipboard Surveys

Figure 8: Detection hierarchy for shipboard surveys

## Low Platforms

The sightings were right truncated at 5500 m .

| Covariate | Description |
| :--- | :--- |
| beaufort | Beaufort sea state. |
| size | Estimated size (number of individuals) of the sighted group. |

## Naked Eye Surveys

Because this taxon was sighted too infrequently to fit a detection function to its sightings alone, we fit a detection function to the pooled sightings of several other species that we believed would exhibit similar detectability. These "proxy species" are listed below.

| Reported By Observer | Common Name | n |
| :--- | :--- | ---: |
| Delphinus capensis | Long-beaked common dolphin | 0 |
| Delphinus delphis | Short-beaked common dolphin | 255 |

| Delphinus delphis/Lagenorhynchus acutus | Short-beaked common or Atlantic white-sided dolphin | 0 |
| :--- | :--- | ---: |
| Delphinus delphis/Stenella | Short-beaked common dolphin or Stenella spp. | 0 |
| Delphinus delphis/Stenella coeruleoalba | Short-beaked common or striped dolphin | 72 |
| Grampus griseus | Risso's dolphin | 9 |
| Grampus griseus/Tursiops truncatus | Risso's or Bottlenose dolphin | 0 |
| Lagenodelphis hosei | Fraser's dolphin | 0 |
| Lagenorhynchus acutus | Atlantic white-sided dolphin | 102 |
| Lagenorhynchus albirostris | White-beaked dolphin | 36 |
| Lagenorhynchus albirostris/Lagenorhynchus acutus | White-beaked or white-sided dolphin | 4 |
| Stenella | Unidentified Stenella | 0 |
| Stenella attenuata | Pantropical spotted dolphin | 0 |
| Stenella attenuata/frontalis | Pantropical or Atlantic spotted dolphin | 0 |
| Stenella clymene | Clymene dolphin | 0 |
| Stenella coeruleoalba | Striped dolphin | 48 |
| Stenella frontalis | Atlantic spotted dolphin | 0 |
| Stenella frontalis/Tursiops truncatus | Atlantic spotted or Bottlenose dolphin | 0 |
| Stenella longirostris | Spinner dolphin | 0 |
| Steno bredanensis | Rough-toothed dolphin | 0 |
| Steno bredanensis/Tursiops truncatus | Bottlenose or rough-toothed dolphin | 0 |
| Tursiops truncatus | Bottlenose dolphin |  |
| Total |  | 067 |

## Without Belly Observers - 600 ft

Because this taxon was sighted too infrequently to fit a detection function to its sightings alone, we fit a detection function to the pooled sightings of several other species that we believed would exhibit similar detectability. These "proxy species" are listed below.

| Reported By Observer | Common Name | n |
| :--- | :--- | :---: |
| Delphinus capensis | Long-beaked common dolphin | 0 |
| Delphinus delphis | Short-beaked common dolphin | 5 |

| Delphinus delphis/Lagenorhynchus acutus | Short-beaked common or Atlantic white-sided dolphin |  |
| :--- | :--- | ---: |
| Delphinus delphis/Stenella | Short-beaked common dolphin or Stenella spp. | 0 |
| Delphinus delphis/Stenella coeruleoalba | Short-beaked common or striped dolphin | 0 |
| Grampus griseus | Risso's dolphin | 0 |
| Grampus griseus/Tursiops truncatus | Risso's or Bottlenose dolphin | 3 |
| Lagenodelphis hosei | Fraser's dolphin | 0 |
| Lagenorhynchus acutus | Atlantic white-sided dolphin | 4 |
| Lagenorhynchus albirostris | White-beaked dolphin | 31 |
| Lagenorhynchus albirostris/Lagenorhynchus acutus | White-beaked or white-sided dolphin | 0 |
| Stenella | Unidentified Stenella | 0 |
| Stenella attenuata | Pantropical spotted dolphin | 0 |
| Stenella attenuata/frontalis | Pantropical or Atlantic spotted dolphin | 4 |
| Stenella clymene | Clymene dolphin | 0 |
| Stenella coeruleoalba | Striped dolphin | 0 |
| Stenella frontalis | Atlantic spotted dolphin | 0 |
| Stenella frontalis/Tursiops truncatus | Atlantic spotted or Bottlenose dolphin | 0 |
| Stenella longirostris | Spinner dolphin | 0 |
| Steno bredanensis | Rough-toothed dolphin | 0 |
| Steno bredanensis/Tursiops truncatus | Bottlenose or rough-toothed dolphin | 0 |
| Tursiops truncatus | Bottlenose dolphin | 0 |
| Total |  | 117 |

## NARWSS Grummans

Because this taxon was sighted too infrequently to fit a detection function to its sightings alone, we fit a detection function to the pooled sightings of several other species that we believed would exhibit similar detectability. These "proxy species" are listed below.

| Reported By Observer | Common Name | n |
| :--- | :--- | ---: |
| Delphinus capensis | Long-beaked common dolphin | 0 |
| Delphinus delphis | Short-beaked common dolphin | 42 |

| Delphinus delphis/Lagenorhynchus acutus | Short-beaked common or Atlantic white-sided dolphin | 0 |
| :--- | :--- | ---: |
| Delphinus delphis/Stenella | Short-beaked common dolphin or Stenella spp. | 0 |
| Delphinus delphis/Stenella coeruleoalba | Short-beaked common or striped dolphin | 0 |
| Grampus griseus | Risso's dolphin | 0 |
| Grampus griseus/Tursiops truncatus | Risso's or Bottlenose dolphin | 0 |
| Lagenodelphis hosei | Fraser's dolphin | 0 |
| Lagenorhynchus acutus | Atlantic white-sided dolphin | 288 |
| Lagenorhynchus albirostris | White-beaked dolphin | 3 |
| Lagenorhynchus albirostris/Lagenorhynchus acutus | White-beaked or white-sided dolphin | 0 |
| Stenella | Unidentified Stenella | 0 |
| Stenella attenuata | Pantropical spotted dolphin | 0 |
| Stenella attenuata/frontalis | Pantropical or Atlantic spotted dolphin | 0 |
| Stenella clymene | Clymene dolphin | 0 |
| Stenella coeruleoalba | Striped dolphin | 1 |
| Stenella frontalis | Atlantic spotted dolphin | 0 |
| Stenella frontalis/Tursiops truncatus | Atlantic spotted or Bottlenose dolphin | 0 |
| Stenella longirostris | Spinner dolphin | 0 |
| Steno bredanensis | Rough-toothed dolphin | 0 |
| Steno bredanensis/Tursiops truncatus | Bottlenose or rough-toothed dolphin |  |
| Tursiops truncatus | Bottlenose dolphin | 0 |
| Total |  | 0 |

Table 35: Proxy species used to fit detection functions for NARWSS Grummans. The number of sightings, n, is before truncation.

The sightings were right truncated at 800 m . Due to a reduced frequency of sightings close to the trackline that plausibly resulted from the behavior of the observers and/or the configuration of the survey platform, the sightings were left truncted as well. Sightings closer than 107 m to the trackline were omitted from the analysis, and it was assumed that the the area closer to the trackline than this was not surveyed. This distance was estimated by inspecting histograms of perpendicular sighting distances.

| Covariate | Description |
| :--- | :--- |
| beaufort | Beaufort sea state. |
| quality | Survey-specific index of the quality of observation conditions, utilizing relevant <br> factors other than Beaufort sea state (see methods). |
| size | Estimated size (number of individuals) of the sighted group. |

Group Size vs. Distance, right trunc. at 2500 m

Figure 69: Histograms showing group size frequency and scatterplots showing the relationship between group size and perpendicular sighting distance, for all sightings (top row) and only those not right truncated (bottom row). In the scatterplot, the line is a simple linear regression.

| Platform | Surveys | Group <br> Size | $g(0)$ | Biases <br> Addressed | Source |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Shipboard | All | 1-20 | 0.856 | Perception | Barlow and Forney (2007) |
|  |  | $>20$ | 0.970 | Perception | Barlow and Forney (2007) |
| Shipboard | NEFSC Abel-J Binocular Surveys | Any | 0.61 | Perception | Palka (2006) |
| Shipboard | NEFSC Endeavor | Any | 0.84 | Perception | Palka (2006) |
| Aerial | All | 1-5 | 0.43 | Both | Palka (2006) |
|  |  | $>5$ | 0.960 | Both | Carretta et al. (2000) |

Table 41: Estimates of $g(0)$ used in this density model.

For shipboard surveys other than the NOAA NEFSC cruises for which Palka (2006) provided survey-specific estimates of $g(0)$, we utilized Barlow and Forney's (2007) estimates for delphinids, produced from several years of dual-team surveys that used similar binoculars and protocols to the surveys in our study. This study provided separate estimates for small and large groups, but pooled sightings of several species together to provide a generic estimate for all delphinids, due to sample-size limitations. To our knowledge, there is no species-specific shipboard $g(0)$ estimate that treats small and large groups separately, so we believe Barlow and Forney (2007) provide the best general- purpose alternative. Their estimate accounted for perception bias but not availability bias; dive times for dolphins are short enough that availability bias is not expected to be significant for dolphins observed from shipboard surveys.

For aerial surveys, we were unable to locate species-specific $g(0)$ estimates in the literature. For small groups, defined here as $1-5$ individuals, we used Palka's (2006) estimate of $g(0)$ for groups of 1-5 small cetaceans, estimated from two years of aerial surveys using the Hiby (1999) circle-back method. This estimate accounted for both availability and perception bias, but pooled sightings of several species together to provide a generic estimate for all delphinids, due to sample-size limitations. For large groups, defined here as greater than 5 individuals, Palka (2006) assumed that $\mathrm{g}(0)$ was 1 . When we discussed this with NOAA SWFSC reviewers, they agreed that it was safe to assume that the availability bias component of $g(0)$ was 1 but insisted that perception bias should be slightly less than 1, because it was possible to miss large groups. We agreed to take a conservative approach and obtained our $g(0)$ for large groups from Carretta et al. (2000), who estimated $g(0)$ for both small and large groups of delphinids. We used Carretta et al.'s $\mathrm{g}(0)$ estimate for groups of 1-25 individuals (0.960), rather than their larger one for more than 25 individuals (0.994), to account for the fact that we were using Palka's definition of large groups as those with more than 5 individuals.

## Density Models

A recent comprehensive review of the global distribution reported that Risso's dolphins "occur in all habitats from coastal to oceanic [but] show a strong preference for the mid-temperate waters of the continental shelf and slope between 30-45 degrees latitude", (Jefferson et al. 2014). This description is consistent with the sightings reported by the surveys we utilized: most sightings occurred on the continental slope close to the shelf break, while fewer sightings occurred on the shelf and in waters deeper than the slope. Little information is available about the seasonal distribution of Risso's dolphins in the study area. The population is reported to occupy the mid-Atlantic continental shelf edge year round, and may expand northward onto the shelf of Georges Bank and into the Gulf of Maine during spring, summer and fall, contracting southward in winter (Waring et al. 2014; CETAP 1982).
Given this year-round presence, we modeled Risso's dolphin abundance with a single, year-round model that incorporated all available survey data. We modeled the shelf and the slope/abyss separately, under the presumption that abundance might relate to different ecological processes in these two areas. Although survey effort off the continental shelf was sparse in non-summer months, we allowed the model to predict off-shelf during all months of the year. These predictions should be viewed with due caution.

Figure 70: Risso's dolphin density model schematic. All on-effort sightings are shown, including those that were truncated when detection functions were fitted.

Climatological Model

Figure 71: Risso's dolphin density predicted by the climatological model that explained the most deviance. Pixels are 10x10 km . The legend gives the estimated individuals per pixel; breaks are logarithmic. Abundance for each region was computed by summing the density cells occuring in that region.

Figure 72: Estimated uncertainty for the climatological model that explained the most deviance. These estimates only incorporate the statistical uncertainty estimated for the spatial model (by the R mgcv package). They do not incorporate uncertainty in the detection functions, $\mathrm{g}(0)$ estimates, predictor variables, and so on.

Diagnostic plots

Figure 87: Segments with predictor values for the Risso's dolphin Contemporaneous model, Shelf. This plot is used to assess how many segments would be lost by including a given predictor in a model.

Figure 88: Statistical diagnostic plots for the Risso's dolphin Contemporaneous model, Shelf.

Figure 89: Scatterplot matrix for the Risso's dolphin Contemporaneous model, Shelf. This plot is used to inspect the distribution of predictors (via histograms along the diagonal), simple correlation between predictors (via pairwise Pearson coefficients above the diagonal), and linearity of predictor correlations (via scatterplots below the diagonal). This plot is best viewed at high magnification.

Figure 90: Dotplot for the Risso's dolphin Contemporaneous model, Shelf. This plot is used to check for suspicious patterns and outliers in the data. Points are ordered vertically by transect ID, sequentially in time.

Climatological Same Segments Model

Figure 91: Risso's dolphin density predicted by the climatological same segments model that explained the most deviance. Pixels are $10 \times 10 \mathrm{~km}$. The legend gives the estimated individuals per pixel; breaks are logarithmic. Abundance for each region was computed by summing the density cells occuring in that region.

Figure 92: Estimated uncertainty for the climatological same segments model that explained the most deviance. These estimates only incorporate the statistical uncertainty estimated for the spatial model (by the R mgcv package). They do not incorporate uncertainty in the detection functions, $g(0)$ estimates, predictor variables, and so on.

## Model Comparison

## Spatial Model Performance

The table below summarizes the performance of the candidate spatial models that were tested. For each subregion, the first model contained only physiographic predictors. Subsequent models added additional suites of predictors of based on when they became available via remote sensing.

For each model, three versions were fitted; the \% Dev Expl columns give the \% deviance explained by each one. The "climatological" models were fitted to 8-day climatologies of the environmental predictors. Because the environmental predictors were always available, no segments were lost, allowing these models to consider the maximal amount of survey data. The "contemporaneous" models were fitted to day-of-sighting images of the environmental predictors; these were smoothed to reduce data loss due to clouds, but some segments still failed to retrieve environmental values and were lost. Finally, the "climatological same segments" models fitted climatological predictors to the segments retained by the contemporaneous model, so that the explantory power of the two types of predictors could be directly compared. For each of the three models, predictors were selected independently via shrinkage smoothers; thus the three models did not necessarily utilize the same predictors.

Predictors derived from ocean currents first became available in January 1993 after the launch of the TOPEX/Poseidon satellite; productivity predictors first became available in September 1997 after the launch of the SeaWiFS sensor. Contemporaneous and climatological same segments models considering these predictors usually suffered data loss. Date Range shows the years spanned by the retained segments. The Segments column gives the number of segments retained; \% Lost gives the percentage lost.

Table 42: Deviance explained by the candidate density models.

## Abundance Estimates

The table below shows the estimated mean abundance (number of animals) within the study area, for the models that explained the most deviance for each model type. Mean abundance was calculated by first predicting density maps for a series of time steps, then computing the abundance for each map, and then averaging the abundances. For the climatological models, we used 8-day climatologies, resulting in 46 abundance maps. For the contemporaneous models, we used daily images, resulting in 365 predicted abundance maps per year that the prediction spanned. The Dates column gives the dates to which the estimates apply. For our models, these are the years for which both survey data and remote sensing data were available.

The Assumed $g(0)=1$ column specifies whether the abundance estimate assumed that detection was certain along the survey trackline. Studies that assumed this did not correct for availability or perception bias, and therefore underestimated abundance. The In our models column specifies whether the survey data from the study was also used in our models. If not, the study
provides a completely independent estimate of abundance.

| Dates | Model or study | Estimated <br> abundance | CV | Assumed <br> $\mathrm{g}(0)=1$ | In our <br> models |

Table 43: Estimated mean abundance within the study area. We selected the model marked with $*$ as our best estimate of the abundance and distribution of this taxon. For comparison, independent abundance estimates from NOAA technical reports and/or the scientific literature are shown. Please see the Discussion section below for our evaluation of our models compared to the other estimates. Note that our abundance estimates are averaged over the whole year, while the other studies may have estimated abundance for specific months or seasons. Our coefficients of variation (CVs) underestimate the true uncertainty in our estimates, as they only incorporated the uncertainty of the GAM stage of our models. Other sources of uncertainty include the detection functions and $\mathrm{g}(0)$ estimates. It was not possible to incorporate these into our CVs without undertaking a computationally-prohibitive bootstrap; we hope to attempt that in a future version of our models.

## Density Maps

Figure 101: Risso's dolphin density and abundance predicted by the climatological model that explained the most deviance. Regions inside the study area (white line) where the background map is visible are areas we did not model (see text).

Figure 102: Risso's dolphin density and abundance predicted by the contemporaneous model that explained the most deviance. Regions inside the study area (white line) where the background map is visible are areas we did not model (see text).

Figure 103: Risso's dolphin density and abundance predicted by the climatological same segments model that explained the most deviance. Regions inside the study area (white line) where the background map is visible are areas we did not model (see text).

## Temporal Variability

Figure 104: Comparison of Risso's dolphin abundance predicted at a daily time step for different time periods. Individual years were predicted using contemporaneous models. "All years (mean)" averages the individual years, giving the mean annual abundance of the contemporaneous model. "Climatological" was predicted using the climatological model. The results for the climatological same segments model are not shown.

Figure 105: The same data as the preceding figure, but with a 30 -day moving average applied.

Contemporaneous Model

Climatological Same Segments Model

## Discussion

The majority of Risso's dolphins were sighted in the Slope and Abyss region. Here, the climatological models achieved better fits than the contemporaneous models, explaining $2.3-4.8 \%$ more deviance, suggesting that climatological predictors are more suitable for modeling Risso's dolphins in this region. In the Shelf region, where fewer Risso's dolphins were sighted, the contemporaneous models achieved better fits, explaining $0.7-2.2 \%$ more deviance than the climatological models.
The predicted mean total abundance ranged widely across the models, with the climatological model that considered all segments predicting the smallest abundance and the other two predicting nearly $70 \%$ more. The models were most similar in the winter months. The greatest differences occurred the late summer months of August and September, with the contemporaneous model predicting much higher abundance along the Scotian Shelf, particularly in the deep Laurentian

Channel leading into the Gulf of St. Lawrence, and a large submarine canyon known as the "Gully" (see Temporal Variability section). We are skeptical of these predictions. Lawson and Gosselin (2009) reported only six sightings of Risso's dolphins on the entire Scotian Shelf and near Cape Breton Island during the Canadian TNASS summer aerial survey in 2007. Hooker et al. (1999) reported no sightings during seven years of vessel-based cetacean research trips to the Gully; all were conducted in June-August months.
We made several attempts to contact J. Lawson regarding the Canadian TNASS survey, in the hope of incorporating it into our models to improve our predictions in Canadian waters, but we received no response. We remain hopeful that a collaboration can be established in the future, and the Canadian TNASS data may be incorporated into a new version of our models.

Prior abundance surveys conducted across the broader east coast of the U.S. and Canada by NOAA estimated 14400-20400 Risso's dolphins for the months of June-August, although the spatial extents of these predictions did not exactly match that of our study area. In comparison, our climatological model that considered all segments predicted 10900-18400, while the contemporaneous model predicted 17800-27500.

Given the climatological model's closer match to NOAA's estimates, and that the contemporaneous model predicted what seemed to be spurious high abundance in Canada, we selected the climatological model that considered all segments as our best estimate of Risso's dolphin distribution and abundance.

We also considered the climatological model that was fitted to the same segments as the contemporaneous model. This model predicted the highest total mean abundance, with June-August abundance ranging from 19700-22700. But this model displayed what we believe is an unlikely "bump" in wintertime abundance, in which abundance was low in November-December, then increased roughly $25 \%$ in January-March, then fell below the November-December level in April-May. For this reason, we preferred the climatological model that was fitted to all segments.

The literature suggested that Risso's dolphins occupy the mid-Atlantic continental shelf edge year round, and may expand northward during spring, summer and fall, contracting southward in winter (Waring et al. 2014; CETAP 1982). Because our model reproduced that pattern, we suggest that our monthly predictions be used for federal regulatory purposes and marine spatial planning applications, so that the seasonality of the species be accounted for. But we urge caution in winter. Our model predicted roughly $85 \%$ lower abundance in January than in August. If this is correct, it suggests that the bulk of the population migrates out of the study area in winter, perhaps south to the Caribbean or far offshore. With so little survey effort off the shelf in winter, we have little evidence on which to base such a claim. To resolve this uncertainty, we strongly recommend that additional off-shelf surveys be performed in winter months.
